## Handlebar Riser Installation Instructions

Please note: There is no need to remove any of the controls attached to the handlebar. The entire assembly can be removed from the handlebar holder and replaced into the new riser.

1. Cover tank with a cloth to protect from scratches.
2. Start on either handlebar by removing the bolt holding the handlebar into the handlebar holder. Note that this bolt should have loctite from the factory so getting it loose will probably take a long wrench for leverage. Don't expect to remove with a small allen wrench.
3. Once the bolt is removed, carefully slide the handlebar out of the holder. Remember, there is no need to remove any of the controls from the handlebar.
4. Gently slide the riser into the hole from which the handlebar was just removed. Make sure the riser seats completely into the hole.
5. Tighten the riser just as you would the handlebar using the appropriate factory torque settings if available.
6. Insert the handlebar into the riser and tighten.
7. Note: You may need to reroute the front brake line by simply taking it out of the wire keeper. You can secure it to the outside of the keeper with a zip tie to eliminate any excess movement.
8. Repeat these steps for the other side and you are all done.

The net results of the risers are a 1.25 inch rise with about a .5 inch pull back.
